

Activity_Course 6 Automatidata project lab

May 11, 2025

1 Automatidata project

Course 6 - The Nuts and bolts of machine learning

You are a data professional in a data analytics firm called Automatidata. Their client, the New York City Taxi & Limousine Commission (New York City TLC), was impressed with the work you have done and has requested that you build a machine learning model to predict if a customer will not leave a tip. They want to use the model in an app that will alert taxi drivers to customers who are unlikely to tip, since drivers depend on tips.

A notebook was structured and prepared to help you in this project. Please complete the following questions.

2 Course 6 End-of-course project: Build a machine learning model

In this activity, you will practice using tree-based modeling techniques to predict on a binary target class.

The purpose of this model is to find ways to generate more revenue for taxi cab drivers.

The goal of this model is to predict whether or not a customer is a generous tipper.

This activity has three parts:

Part 1: Ethical considerations * Consider the ethical implications of the request

- Should the objective of the model be adjusted?

Part 2: Feature engineering

- Perform feature selection, extraction, and transformation to prepare the data for modeling

Part 3: Modeling

- Build the models, evaluate them, and advise on next steps

Follow the instructions and answer the questions below to complete the activity. Then, complete an Executive Summary using the questions listed on the PACE Strategy Document.

Be sure to complete this activity before moving on. The next course item will provide you with a completed exemplar to compare to your own work.

3 Build a machine learning model

4 PACE stages

Throughout these project notebooks, you'll see references to the problem-solving framework PACE. The following notebook components are labeled with the respective PACE stage: Plan, Analyze, Construct, and Execute.

4.1 PACE: Plan

Consider the questions in your PACE Strategy Document to reflect on the Plan stage.

In this stage, consider the following questions:

1. What are you being asked to do?
2. What are the ethical implications of the model? What are the consequences of your model making errors?
 - What is the likely effect of the model when it predicts a false negative (i.e., when the model says a customer will give a tip, but they actually won't)?
 - What is the likely effect of the model when it predicts a false positive (i.e., when the model says a customer will not give a tip, but they actually will)?
3. Do the benefits of such a model outweigh the potential problems?
4. Would you proceed with the request to build this model? Why or why not?
5. Can the objective be modified to make it less problematic?
 1. Predict if the customer will give a tip or not.
 2. There are possible scenarios that could happen if the customer will/won't give a tip. If the customer don't give a tip and the driver told them that it's mandatory, it could lead to bad experience. This is a one scenario from many others.
 3. The drivers shouldn't select the customers to avoid problems.
 4. No, it's always important to find a balance.
 5. There could be a score for the driver and the customer based on their attitude or other features, including the tip, this could help to let both parties to see who will be in the trip.

Suppose you were to modify the modeling objective so, instead of predicting people who won't tip at all, you predicted people who are particularly generous—those who will tip 20% or more? Consider the following questions:

1. What features do you need to make this prediction?
2. What would be the target variable?
3. What metric should you use to evaluate your model? Do you have enough information to decide this now?
 1. The history from the customers, including every detail of the trip and tip amount.
 2. A binary variable (0 a 1). If the customer give a tip above 20% (1), and if not (0)
 3. F1, precession, recall, and accuracy.

Complete the following steps to begin:

4.1.1 Task 1. Imports and data loading

Import packages and libraries needed to build and evaluate random forest and XGBoost classification models.

```
[1]: # Import packages and libraries
    ### YOUR CODE HERE ###
    import numpy as np
    import pandas as pd

    import matplotlib.pyplot as plt

    from sklearn.model_selection import GridSearchCV, train_test_split
    from sklearn.metrics import roc_auc_score, roc_curve
    from sklearn.metrics import accuracy_score, precision_score, recall_score, \
    f1_score, confusion_matrix, ConfusionMatrixDisplay, RocCurveDisplay

    from sklearn.ensemble import RandomForestClassifier
    from xgboost import XGBClassifier

    from xgboost import plot_importance
```

```
[2]: # RUN THIS CELL TO SEE ALL COLUMNS
    # This lets us see all of the columns, preventing Jupyter from redacting them.
    pd.set_option('display.max_columns', None)
```

Begin by reading in the data. There are two dataframes: one containing the original data, the other containing the mean durations, mean distances, and predicted fares from the previous course's project called `nyc_preds_means.csv`.

Note: Pandas reads in the dataset as `df0`, now inspect the first five rows. As shown in this cell, the dataset has been automatically loaded in for you. You do not need to download the .csv file, or provide more code, in order to access the dataset and proceed with this lab. Please continue with this activity by completing the following instructions.

```
[3]: # RUN THE CELL BELOW TO IMPORT YOUR DATA.

    # Load dataset into dataframe
    df0 = pd.read_csv('2017_Yellow_Taxi_Trip_Data.csv')

    # Import predicted fares and mean distance and duration from previous course
    nyc_preds_means = pd.read_csv('nyc_preds_means.csv')
```

Inspect the first few rows of `df0`.

```
[4]: # Inspect the first few rows of df0
    ### YOUR CODE HERE ###
```

```
df0.head()
```

```

dtypes: float64(11), int64(7), object(3)
memory usage: 3.6+ MB

```

You know from your EDA that customers who pay cash generally have a tip amount of \$0. To meet the modeling objective, you'll need to sample the data to select only the customers who pay with credit card.

Copy `df0` and assign the result to a variable called `df1`. Then, use a Boolean mask to filter `df1` so it contains only customers who paid with credit card.

```

[8]: # Subset the data to isolate only customers who paid by credit card
#==> ENTER YOUR CODE HERE
df1 = df0[df0['payment_type'] == 1]

```

Target Notice that there isn't a column that indicates tip percent, which is what you need to create the target variable. You'll have to engineer it.

Add a `tip_percent` column to the dataframe by performing the following calculation:

$$\text{tip percent} = \frac{\text{tip amount}}{\text{total amount} - \text{tip amount}}$$

Round the result to three places beyond the decimal. **This is an important step.** It affects how many customers are labeled as generous tippers. In fact, without performing this step, approximately 1,800 people who do tip 20% would be labeled as not generous.

To understand why, you must consider how floats work. Computers make their calculations using floating-point arithmetic (hence the word "float"). Floating-point arithmetic is a system that allows computers to express both very large numbers and very small numbers with a high degree of precision, encoded in binary. However, precision is limited by the number of bits used to represent a number, which is generally 32 or 64, depending on the capabilities of your operating system.

This comes with limitations in that sometimes calculations that should result in clean, precise values end up being encoded as very long decimals. Take, for example, the following calculation:

```

[9]: # Run this cell
1.1 + 2.2

```

```

[9]: 3.3000000000000003

```

Notice the three that is 16 places to the right of the decimal. As a consequence, if you were to then have a step in your code that identifies values `> 3.3`, this would not be included in the result. Therefore, whenever you perform a calculation to compute a number that is then used to make an important decision or filtration, round the number. How many degrees of precision you round to is your decision, which should be based on your use case.

Refer to this [guide for more information related to floating-point arithmetic](#).

```
[10]: # Create tip % col
#==> ENTER YOUR CODE HERE
df1['tip_percent'] = round(df1['tip_amount'] / (df1['total_amount'] -
↳df1['tip_amount']), 3)
```

Now create another column called `generous`. This will be the target variable. The column should be a binary indicator of whether or not a customer tipped `> 20%` (0=no, 1=yes).

1. Begin by making the `generous` column a copy of the `tip_percent` column.
2. Reassign the column by converting it to Boolean (True/False).
3. Reassign the column by converting Boolean to binary (1/0).

```
[11]: # Create 'generous' col (target)
#==> ENTER YOUR CODE HERE
df1['generous'] = df1['tip_percent']
df1['generous'] = (df1['generous'] >= 0.20)
df1['generous'] = df1['generous'].astype(int)
```

HINT

To convert from Boolean to binary, use `.astype(int)` on the column.

Create day column Next, you're going to be working with the pickup and dropoff columns.

Convert the `tpep_pickup_datetime` and `tpep_dropoff_datetime` columns to datetime.

```
[12]: # Convert pickup and dropoff cols to datetime
#==> ENTER YOUR CODE HERE
df1['tpep_pickup_datetime'] = pd.to_datetime(df1['tpep_pickup_datetime'],
↳format='%m/%d/%Y %I:%M:%S %p')
df1['tpep_dropoff_datetime'] = pd.to_datetime(df1['tpep_dropoff_datetime'],
↳format='%m/%d/%Y %I:%M:%S %p')
```

Create a `day` column that contains only the day of the week when each passenger was picked up. Then, convert the values to lowercase.

```
[13]: # Create a 'day' col
#==> ENTER YOUR CODE HERE
df1['day'] = df1['tpep_pickup_datetime'].dt.day_name().str.lower()
```

HINT

To convert to day name, use `dt.day_name()` on the column.

Create time of day columns Next, engineer four new columns that represent time of day bins. Each column should contain binary values (0=no, 1=yes) that indicate whether a trip began (picked up) during the following times:

```
am_rush = [06:00–10:00)
daytime = [10:00–16:00)
pm_rush = [16:00–20:00)
nighttime = [20:00–06:00)
```

To do this, first create the four columns. For now, each new column should be identical and contain the same information: the hour (only) from the `tpep_pickup_datetime` column.

```
[14]: # Create 'am_rush' col
      #==> ENTER YOUR CODE HERE
df1['am_rush'] = df1['tpep_pickup_datetime'].dt.hour
      # Create 'daytime' col
      #==> ENTER YOUR CODE HERE
df1['daytime'] = df1['tpep_pickup_datetime'].dt.hour
      # Create 'pm_rush' col
      #==> ENTER YOUR CODE HERE
df1['pm_rush'] = df1['tpep_pickup_datetime'].dt.hour
      # Create 'nighttime' col
      #==> ENTER YOUR CODE HERE
df1['nighttime'] = df1['tpep_pickup_datetime'].dt.hour
```

You'll need to write four functions to convert each new column to binary (0/1). Begin with `am_rush`. Complete the function so if the hour is between [06:00–10:00), it returns 1, otherwise, it returns 0.

```
[15]: # Define 'am_rush()' conversion function [06:00–10:00)
      #==> ENTER YOUR CODE HERE
def am_rush(hour):
    if 6 <= hour['am_rush'] <= 10:
        val = 1
    else:
        val = 0
    return val
```

Now, apply the `am_rush()` function to the `am_rush` series to perform the conversion. Print the first five values of the column to make sure it did what you expected it to do.

Note: Be careful! If you run this cell twice, the function will be reapplied and the values will all be changed to 0.

```
[16]: # Apply 'am_rush' function to the 'am_rush' series
      #==> ENTER YOUR CODE HERE
df1['am_rush'] = df1.apply(am_rush, axis = 1)
df1['am_rush'].head(5)
```

```
[16]: 0    1
      1    0
      2    1
      3    0
      5    0
      Name: am_rush, dtype: int64
```

Write functions to convert the three remaining columns and apply them to their respective series.

```
[17]: # Define 'daytime()' conversion function [10:00-16:00)
      #==> ENTER YOUR CODE HERE
      def daytime(hour):
          if 10 <= hour['daytime'] <= 16:
              val = 1
          else:
              val = 0
          return val
```

```
[18]: # Apply 'daytime()' function to the 'daytime' series
      #==> ENTER YOUR CODE HERE
      df1['daytime'] = df1.apply(daytime, axis = 1)
      df1['daytime'].head(5)
```

```
[18]: 0    0
      1    1
      2    0
      3    1
      5    0
      Name: daytime, dtype: int64
```

```
[19]: # Define 'pm_rush()' conversion function [16:00-20:00)
      #==> ENTER YOUR CODE HERE
      def pm_rush(hour):
          if 16 <= hour['pm_rush'] <= 20:
              val = 1
          else:
              val = 0
          return val
```

```
[20]: # Apply 'pm_rush()' function to the 'pm_rush' series
      #==> ENTER YOUR CODE HERE
      df1['pm_rush'] = df1.apply(pm_rush, axis = 1)
      df1['pm_rush'].head(5)
```

```
[20]: 0    0
      1    0
      2    0
```

```
3    0
5    1
Name: pm_rush, dtype: int64
```

```
[21]: # Define 'nighttime()' conversion function [20:00-06:00)
#==> ENTER YOUR CODE HERE
def nighttime(hour):
    if 16 <= hour['nighttime'] <= 20:
        val = 1
    else:
        val = 0
    return val
```

```
[22]: # Apply 'nighttime' function to the 'nighttime' series
#==> ENTER YOUR CODE HERE
df1['nighttime'] = df1.apply(nighttime, axis = 1)
df1['nighttime'].head(5)
```

```
[22]: 0    0
1    0
2    0
3    0
5    1
Name: nighttime, dtype: int64
```

Create month column Now, create a `month` column that contains only the abbreviated name of the month when each passenger was picked up, then convert the result to lowercase.

HINT

Refer to the [strftime cheatsheet](#) for help.

```
[23]: # Create 'month' col
#==> ENTER YOUR CODE HERE
df1['month'] = df1['tpep_pickup_datetime'].dt.strftime('%b').str.lower()
```

Examine the first five rows of your dataframe.

```
[24]: #==> ENTER YOUR CODE HERE
df1.head()
```

```

Drop columns Drop redundant and irrelevant columns as well as those that would not be available when the model is deployed. This includes information like payment type, trip distance, tip amount, tip percentage, total amount, toll amount, etc. The target variable (**generous**) must remain in the data because it will get isolated as the y data for modeling.

```
[25]: # Drop columns
#==> ENTER YOUR CODE HERE
drop_cols = ['Unnamed: 0', 'tpep_pickup_datetime', 'tpep_dropoff_datetime',
            'payment_type', 'trip_distance', 'store_and_fwd_flag',
            'payment_type',
            'fare_amount', 'extra', 'mta_tax', 'tip_amount', 'tolls_amount',
            'improvement_surcharge', 'total_amount', 'tip_percent']
```

```
df1 = df1.drop(drop_cols, axis=1)
df1.info()
```

```
<class 'pandas.core.frame.DataFrame'>
Index: 15265 entries, 0 to 22698
Data columns (total 15 columns):
#   Column                Non-Null Count  Dtype

14  month                 15265 non-null  object
dtypes: float64(3), int64(10), object(2)
memory usage: 1.9+ MB
```

Variable encoding Many of the columns are categorical and will need to be dummied (converted to binary). Some of these columns are numeric, but they actually encode categorical information, such as `RatecodeID` and the pickup and dropoff locations. To make these columns recognizable to the `get_dummies()` function as categorical variables, you'll first need to convert them to `type(str)`.

1. Define a variable called `cols_to_str`, which is a list of the numeric columns that contain categorical information and must be converted to string: `RatecodeID`, `PULocationID`, `DOLocationID`.
2. Write a for loop that converts each column in `cols_to_str` to string.

```
[26]: # 1. Define list of cols to convert to string
      #==> ENTER YOUR CODE HERE
      cols_to_str = ['RatecodeID', 'PULocationID', 'DOLocationID', 'VendorID']
      # 2. Convert each column to string
      #==> ENTER YOUR CODE HERE
      for col in cols_to_str:
          df1[col] = df1[col].astype('str')
```

HINT

To convert to string, use `astype(str)` on the column.

Now convert all the categorical columns to binary.

1. Call `get_dummies()` on the dataframe and assign the results back to a new dataframe called `df2`.

```
[27]: # Convert categorical to binary
#==> ENTER YOUR CODE HERE
df2 = pd.get_dummies(df1, drop_first = True)
df2.info()
```

```
<class 'pandas.core.frame.DataFrame'>
Index: 15265 entries, 0 to 22698
Columns: 347 entries, passenger_count to month_sep
dtypes: bool(338), float64(3), int64(6)
memory usage: 6.1 MB
```

Evaluation metric Before modeling, you must decide on an evaluation metric.

1. Examine the class balance of your target variable.

```
[28]: # Get class balance of 'generous' col
#==> ENTER YOUR CODE HERE
df2['generous'].value_counts(normalize = True)
```

```
[28]: generous
1    0.526368
0    0.473632
Name: proportion, dtype: float64
```

A little over half of the customers in this dataset were “generous” (tipped 20%). The dataset is very nearly balanced.

To determine a metric, consider the cost of both kinds of model error: * False positives (the model predicts a tip 20%, but the customer does not give one) * False negatives (the model predicts a tip < 20%, but the customer gives more)

False positives are worse for cab drivers, because they would pick up a customer expecting a good tip and then not receive one, frustrating the driver.

False negatives are worse for customers, because a cab driver would likely pick up a different customer who was predicted to tip more—even when the original customer would have tipped generously.

The stakes are relatively even. You want to help taxi drivers make more money, but you don’t want this to anger customers. Your metric should weigh both precision and recall equally. Which metric is this?

F1

4.3 PACE: Construct

Consider the questions in your PACE Strategy Document to reflect on the Construct stage.

4.3.1 Task 3. Modeling

Split the data Now you're ready to model. The only remaining step is to split the data into features/target variable and training/testing data.

1. Define a variable `y` that isolates the target variable (`generous`).
2. Define a variable `X` that isolates the features.
3. Split the data into training and testing sets. Put 20% of the samples into the test set, stratify the data, and set the random state.

```
[29]: # Isolate target variable (y)
      #==> ENTER YOUR CODE HERE
      y = df2['generous']
      # Isolate the features (X)
      #==> ENTER YOUR CODE HERE
      X = df2.drop('generous', axis=1)
      # Split into train and test sets
      #==> ENTER YOUR CODE HERE
      X_train, X_test, y_train, y_test = train_test_split(X, y, stratify=y,
      ↪test_size=0.2, random_state=42)
```

Random forest Begin with using `GridSearchCV` to tune a random forest model.

1. Instantiate the random forest classifier `rf` and set the random state.
2. Create a dictionary `cv_params` of any of the following hyperparameters and their corresponding values to tune. The more you tune, the better your model will fit the data, but the longer it will take.
 - `max_depth`
 - `max_features`
 - `max_samples`
 - `min_samples_leaf`
 - `min_samples_split`
 - `n_estimators`
3. Define a set `scoring` of scoring metrics for `GridSearch` to capture (precision, recall, F1 score, and accuracy).
4. Instantiate the `GridSearchCV` object `rf1`. Pass to it as arguments:
 - `estimator=rf`
 - `param_grid=cv_params`
 - `scoring=scoring`
 - `cv`: define the number of you cross-validation folds you want (`cv=_`)
 - `refit`: indicate which evaluation metric you want to use to select the model (`refit=_`)

Note: `refit` should be set to `'f1'`.

```
[30]: # 1. Instantiate the random forest classifier
#==> ENTER YOUR CODE HERE
rf = RandomForestClassifier(random_state=42)
# 2. Create a dictionary of hyperparameters to tune
#==> ENTER YOUR CODE HERE
cv_params = {'max_depth': [None],
             'max_features': [1.0],
             'max_samples': [0.7],
             'min_samples_leaf': [1],
             'min_samples_split': [2],
             'n_estimators': [300]
            }
# 3. Define a list of scoring metrics to capture
#==> ENTER YOUR CODE HERE
scoring = ['accuracy', 'precision', 'recall', 'f1']
# 4. Instantiate the GridSearchCV object
#==> ENTER YOUR CODE HERE
rf1 = GridSearchCV(rf, cv_params, scoring=scoring, cv=4, refit='f1')
```

Now fit the model to the training data. Note that, depending on how many options you include in your search grid and the number of cross-validation folds you select, this could take a very long time—even hours. If you use 4-fold validation and include only one possible value for each hyperparameter and grow 300 trees to full depth, it should take about 5 minutes. If you add another value for GridSearch to check for, say, `min_samples_split` (so all hyperparameters now have 1 value except for `min_samples_split`, which has 2 possibilities), it would double the time to ~10 minutes. Each additional parameter would approximately double the time.

```
[31]: #==> ENTER YOUR CODE HERE
rf1.fit(X_train, y_train)
```

```
[31]: GridSearchCV(cv=4, estimator=RandomForestClassifier(random_state=42),
                  param_grid={'max_depth': [None], 'max_features': [1.0],
                              'max_samples': [0.7], 'min_samples_leaf': [1],
                              'min_samples_split': [2], 'n_estimators': [300]},
                  refit='f1', scoring=['accuracy', 'precision', 'recall', 'f1'])
```

HINT

If you get a warning that a metric is 0 due to no predicted samples, think about how many features you're sampling with `max_features`. How many features are in the dataset? How many are likely predictive enough to give good predictions within the number of splits you've allowed (determined by the `max_depth` hyperparameter)? Consider increasing `max_features`.

If you want, use `pickle` to save your models and read them back in. This can be particularly helpful when performing a search over many possible hyperparameter values.

```
[32]: import pickle

# Define a path to the folder where you want to save the model
```

```
path = '/home/jovyan/work/'
```

```
[33]: def write_pickle(path, model_object, save_name:str):  
      '''  
      save_name is a string.  
      '''  
      with open(path + save_name + '.pickle', 'wb') as to_write:  
          pickle.dump(model_object, to_write)
```

```
[34]: def read_pickle(path, saved_model_name:str):  
      '''  
      saved_model_name is a string.  
      '''  
      with open(path + saved_model_name + '.pickle', 'rb') as to_read:  
          model = pickle.load(to_read)  
  
      return model
```

Examine the best average score across all the validation folds.

```
[35]: # Examine best score  
      #==> ENTER YOUR CODE HERE  
      rf1.best_score_
```

```
[35]: 0.7148297531470578
```

Examine the best combination of hyperparameters.

```
[36]: #==> ENTER YOUR CODE HERE  
      rf1.best_params_
```

```
[36]: {'max_depth': None,  
      'max_features': 1.0,  
      'max_samples': 0.7,  
      'min_samples_leaf': 1,  
      'min_samples_split': 2,  
      'n_estimators': 300}
```

Use the `make_results()` function to output all of the scores of your model. Note that it accepts three arguments.

HINT

To learn more about how this function accesses the cross-validation results, refer to the [GridSearchCV scikit-learn documentation](#) for the `cv_results_` attribute.

```
[37]: def make_results(model_name:str, model_object, metric:str):  
      '''  
      Arguments:
```

```

    model_name (string): what you want the model to be called in the output_
↪table
    model_object: a fit GridSearchCV object
    metric (string): precision, recall, f1, or accuracy

    Returns a pandas df with the F1, recall, precision, and accuracy scores
    for the model with the best mean 'metric' score across all validation folds.
    '''

    # Create dictionary that maps input metric to actual metric name in_
↪GridSearchCV
    metric_dict = {'precision': 'mean_test_precision',
                  'recall': 'mean_test_recall',
                  'f1': 'mean_test_f1',
                  'accuracy': 'mean_test_accuracy',
                  }

    # Get all the results from the CV and put them in a df
    cv_results = pd.DataFrame(model_object.cv_results_)

    # Isolate the row of the df with the max(metric) score
    best_estimator_results = cv_results.iloc[cv_results[metric_dict[metric]].
↪idxmax(), :]

    # Extract Accuracy, precision, recall, and f1 score from that row
    f1 = best_estimator_results.mean_test_f1
    recall = best_estimator_results.mean_test_recall
    precision = best_estimator_results.mean_test_precision
    accuracy = best_estimator_results.mean_test_accuracy

    # Create table of results
    table = pd.DataFrame({'model': [model_name],
                          'precision': [precision],
                          'recall': [recall],
                          'F1': [f1],
                          'accuracy': [accuracy],
                          },
                          )

    return table

```

Call `make_results()` on the `GridSearch` object.

```

[38]: #==> ENTER YOUR CODE HERE
results = make_results('RF CV', rf1, 'f1')
results

```

```
[38]:      model  precision    recall  F1   accuracy
      0  RF CV    0.675733  0.759023  0.71483  0.681461
```

Your results should produce an acceptable model across the board. Typically scores of 0.65 or better are considered acceptable, but this is always dependent on your use case. Optional: try to improve the scores. It's worth trying, especially to practice searching over different hyperparameters.

HINT

For example, if the available values for `min_samples_split` were [2, 3, 4] and GridSearch identified the best value as 4, consider trying [4, 5, 6] this time.

Use your model to predict on the test data. Assign the results to a variable called `rf_preds`.

HINT

You cannot call `predict()` on the GridSearchCV object directly. You must call it on the `best_estimator_`.

For this project, you will use several models to predict on the test data. Remember that this decision comes with a trade-off. What is the benefit of this? What is the drawback?

An advantage of using several models is that you can compare it. A disadvantage of using the final test data to select a model is that, by using the unseen data to make a decision about which model to use, you no longer have a truly unbiased idea of how your model would be expected to perform on new data. In this case, think of final model selection as another way of “tuning” your model.

```
[39]: # Get scores on test data
      #==> ENTER YOUR CODE HERE
      rf_preds = rf1.best_estimator_.predict(X_test)
```

Use the below `get_test_scores()` function you will use to output the scores of the model on the test data.

```
[40]: def get_test_scores(model_name:str, preds, y_test_data):
      '''
      Generate a table of test scores.

      In:
      model_name (string): Your choice: how the model will be named in the output_
      ↪table
      preds: numpy array of test predictions
      y_test_data: numpy array of y_test data

      Out:
      table: a pandas df of precision, recall, f1, and accuracy scores for your_
      ↪model
      '''
      accuracy = accuracy_score(y_test_data, preds)
      precision = precision_score(y_test_data, preds)
      recall = recall_score(y_test_data, preds)
```

```

f1 = f1_score(y_test_data, preds)

table = pd.DataFrame({'model': [model_name],
                      'precision': [precision],
                      'recall': [recall],
                      'F1': [f1],
                      'accuracy': [accuracy]
                      })

return table

```

1. Use the `get_test_scores()` function to generate the scores on the test data. Assign the results to `rf_test_scores`.
2. Call `rf_test_scores` to output the results.

RF test results

```

[41]: # Get scores on test data
      #==> ENTER YOUR CODE HERE
      rf_test_scores = get_test_scores('RF test', rf_preds, y_test)
      results = pd.concat([results, rf_test_scores], axis=0)
      results

```

```

[41]:      model  precision    recall      F1  accuracy
0   RF CV    0.675733  0.759023  0.714830  0.681461
0  RF test    0.672069  0.774113  0.719491  0.682280

```

Question: How do your test results compare to your validation results?

Most of the scores increases a little bit.

XGBoost Try to improve your scores using an XGBoost model.

1. Instantiate the XGBoost classifier `xgb` and set `objective='binary:logistic'`. Also set the random state.
2. Create a dictionary `cv_params` of the following hyperparameters and their corresponding values to tune:
 - `max_depth`
 - `min_child_weight`
 - `learning_rate`
 - `n_estimators`
3. Define a set `scoring` of scoring metrics for grid search to capture (precision, recall, F1 score, and accuracy).
4. Instantiate the `GridSearchCV` object `xgb1`. Pass to it as arguments:
 - `estimator=xgb`
 - `param_grid=cv_params`
 - `scoring=scoring`

- cv: define the number of cross-validation folds you want (cv=_)
- refit: indicate which evaluation metric you want to use to select the model (refit='f1')

```
[42]: # 1. Instantiate the XGBoost classifier
#==> ENTER YOUR CODE HERE
xgb = XGBClassifier(objective='binary:logistic', random_state=0)
# 2. Create a dictionary of hyperparameters to tune
#==> ENTER YOUR CODE HERE
cv_params = {'learning_rate': [0.1],
             'max_depth': [8],
             'min_child_weight': [2],
             'n_estimators': [500]
            }
# 3. Define a list of scoring metrics to capture
#==> ENTER YOUR CODE HERE
scoring = ['accuracy', 'precision', 'recall', 'f1']
# 4. Instantiate the GridSearchCV object
#==> ENTER YOUR CODE HERE
xgb1 = GridSearchCV(xgb, cv_params, scoring=scoring, cv=4, refit='f1')
```

Now fit the model to the X_train and y_train data.

```
[43]: %%time
#==> ENTER YOUR CODE HERE
xgb1.fit(X_train, y_train)
```

CPU times: user 23.1 s, sys: 156 ms, total: 23.2 s

Wall time: 12.1 s

```
[43]: GridSearchCV(cv=4,
                  estimator=XGBClassifier(base_score=None, booster=None,
                                          callbacks=None, colsample_bylevel=None,
                                          colsample_bynode=None,
                                          colsample_bytree=None, device=None,
                                          early_stopping_rounds=None,
                                          enable_categorical=False, eval_metric=None,
                                          feature_types=None, gamma=None,
                                          grow_policy=None, importance_type=None,
                                          interaction_constraints=None,
                                          learning_rate=None, ...
                                          max_delta_step=None, max_depth=None,
                                          max_leaves=None, min_child_weight=None,
                                          missing=nan, monotone_constraints=None,
                                          multi_strategy=None, n_estimators=None,
                                          n_jobs=None, num_parallel_tree=None,
                                          random_state=0, ...),
                  param_grid={'learning_rate': [0.1], 'max_depth': [8],
                              'min_child_weight': [2], 'n_estimators': [500]}),
```

```
refit='f1', scoring=['accuracy', 'precision', 'recall', 'f1'])
```

Get the best score from this model.

```
[44]: # Examine best score
      #==> ENTER YOUR CODE HERE
      xgb1.best_score_
```

```
[44]: 0.6920840617116664
```

And the best parameters.

```
[45]: # Examine best parameters
      #==> ENTER YOUR CODE HERE
      xgb1.best_params_
```

```
[45]: {'learning_rate': 0.1,
      'max_depth': 8,
      'min_child_weight': 2,
      'n_estimators': 500}
```

XGB CV Results Use the `make_results()` function to output all of the scores of your model. Note that it accepts three arguments.

```
[46]: # Call 'make_results()' on the GridSearch object
      #==> ENTER YOUR CODE HERE
      xgb1_cv_results = make_results('XGB CV', xgb1, 'f1')
      results = pd.concat([results, xgb1_cv_results], axis=0)
      results
```

```
[46]:      model  precision    recall      F1  accuracy
0    RF CV   0.675733  0.759023  0.714830  0.681461
0  RF test   0.672069  0.774113  0.719491  0.682280
0   XGB CV   0.669775  0.716086  0.692084  0.664592
```

Use your model to predict on the test data. Assign the results to a variable called `xgb_preds`.

HINT

You cannot call `predict()` on the `GridSearchCV` object directly. You must call it on the `best_estimator_`.

```
[47]: # Get scores on test data
      #==> ENTER YOUR CODE HERE
      xgb_preds = xgb1.best_estimator_.predict(X_test)
```

XGB test results

1. Use the `get_test_scores()` function to generate the scores on the test data. Assign the results to `xgb_test_scores`.

2. Call `xgb_test_scores` to output the results.

```
[48]: # Get scores on test data
#==> ENTER YOUR CODE HERE
xgb_test_scores = get_test_scores('XGB test', xgb_preds, y_test)
results = pd.concat([results, xgb_test_scores], axis=0)
results
```

```
[48]:      model precision    recall      F1  accuracy
0    RF CV    0.675733  0.759023  0.714830  0.681461
0  RF test    0.672069  0.774113  0.719491  0.682280
0    XGB CV    0.669775  0.716086  0.692084  0.664592
0  XGB test    0.672241  0.750467  0.709203  0.676056
```

Question: Compare these scores to the random forest test scores. What do you notice? Which model would you choose?

In XGB, the scores are a little bit lower, thus, random forest is suitable.

Plot a confusion matrix of the model's predictions on the test data.

```
[49]: # Generate array of values for confusion matrix
#==> ENTER YOUR CODE HERE
cm = confusion_matrix(y_test, rf_preds, labels=rf1.classes_)
# Plot confusion matrix
#==> ENTER YOUR CODE HERE
disp = ConfusionMatrixDisplay(confusion_matrix=cm,
                              display_labels=rf1.classes_,
                              )
disp.plot(values_format='');
```

Question: What type of errors are more common for your model?

The model is almost twice as likely to predict a false positive than it is to predict a false negative. Therefore, type I errors are more common. This is less desirable, because it's better for a driver to be pleasantly surprised by a generous tip when they weren't expecting one than to be disappointed by a low tip when they were expecting a generous one. However, the overall performance of this model is satisfactory

Feature importance Use the `feature_importances_` attribute of the best estimator object to inspect the features of your final model. You can then sort them and plot the most important ones.

```
[50]: #==> ENTER YOUR CODE HERE
importances = rf1.best_estimator_.feature_importances_
rf_importances = pd.Series(importances, index=X_test.columns)
rf_importances = rf_importances.sort_values(ascending=False)[:15]

fig, ax = plt.subplots(figsize=(8,5))
rf_importances.plot.bar(ax=ax)
ax.set_title('Feature importances')
ax.set_ylabel('Mean decrease in impurity')
fig.tight_layout();
```

4.4 PACE: Execute

Consider the questions in your PACE Strategy Document to reflect on the Execute stage.

4.4.1 Task 4. Conclusion

In this step, use the results of the models above to formulate a conclusion. Consider the following questions:

1. **Would you recommend using this model? Why or why not?**
2. **What was your model doing? Can you explain how it was making predictions?**
3. **Are there new features that you can engineer that might improve model performance?**
4. **What features would you want to have that would likely improve the performance of your model?**

Remember, sometimes your data simply will not be predictive of your chosen target. This is common. Machine learning is a powerful tool, but it is not magic. If your data does not contain predictive signal, even the most complex algorithm will not be able to deliver consistent and accurate predictions. Do not be afraid to draw this conclusion. Even if you cannot use the model to make strong predictions, was the work done in vain? Consider any insights that you could report back to stakeholders.

Congratulations! You've completed this lab. However, you may not notice a green check mark next to this item on Coursera's platform. Please continue your progress regardless of the check

mark. Just click on the “save” icon at the top of this notebook to ensure your work has been logged.
